LE Ginkgo biloba et son action prolongée de 24h.

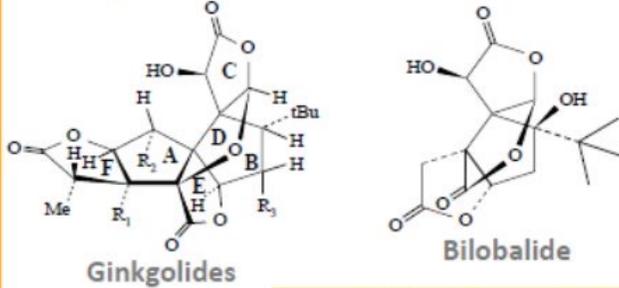

GINKGOATAE: AN UNMODIFIED PHYLUM THROUGH THE CENTURIES

MAIN ACTIVES OF THE CLINICALLY TESTED STANDARDIZED EXTRACT

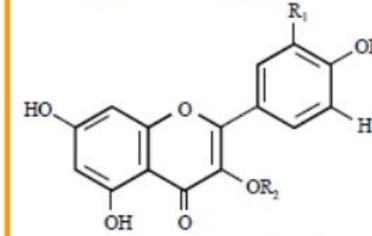

Main terpenic constituents of *Ginkgo biloba* standardized extract

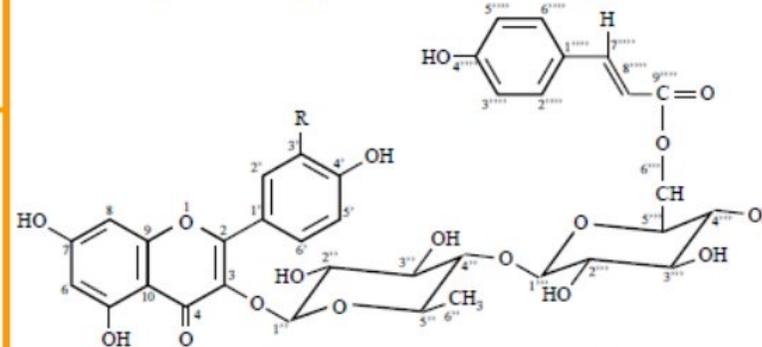

Ginkgolide	R ₁	R ₂	R ₃
A	OH	H	H
B	OH	OH	H
C	OH	OH	OH
J	OH	H	OH
M	H	OH	OH

Ginkgoflavonglycosides

	R ₁	R ₂
1) Astragalin	H	Gl
2) Rutin	OH	Gl-Rh
3) Isorutin	OH	Rh-Gl
4) Kaempferol-3-O-Gl-Rh	H	Gl-Rh
5) Kaempferol-7-O-Gl	H	Gl
6) Isoquercitrin	OH	Gl
7) Isorhamnetin-3-O-Rh-Rh-Gl	OCH ₃	Rh-Rh-Gl
8) Quercetin-3-O-Rh-Rh-Gl	OH	Rh-Rh-Gl

Ginkgoflavonglycosides coumaroyl esters

	R
9) Kaempferol-3-O-α-(6'' coumaroyl)glucosyl-β-1,4-rhamnoside	H
10) Quercetin-3-O-α-(6'' coumaroyl)glucosyl-β-1,4-rhamnoside	OH
11) Isorhamnetin-3-O-α-(6'' coumaroyl)glucosyl-β-1,4-rhamnoside	OCH ₃

≥24% of ginkgoflavogluco-sides by HPLC

≥6% as sum of ginkgolides A, B,C and bilobalide by HPLC

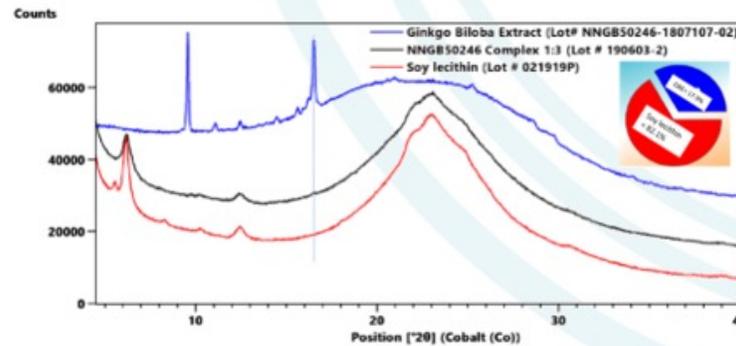

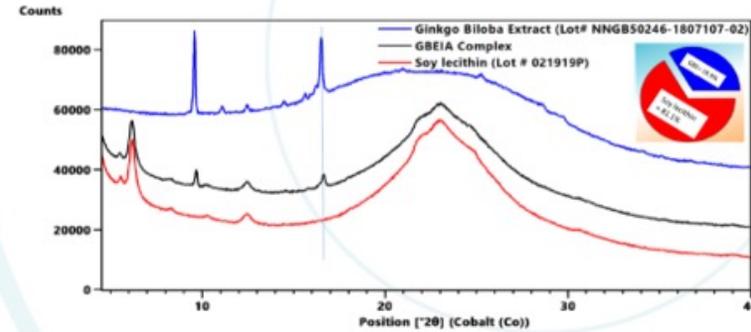

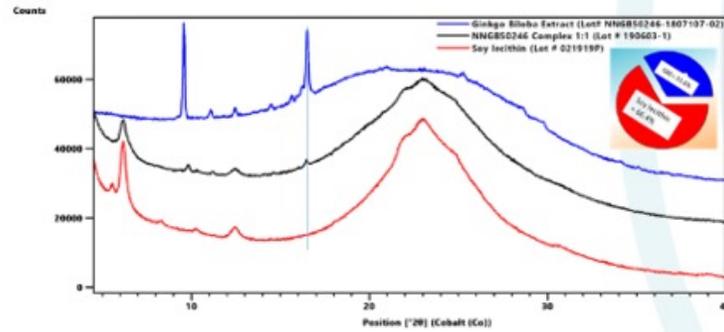

≤5 ppm of total ginkgolic acids by HPLC

Network Nutrition®

Part of IMCD

X-Ray Diffraction (XRD) scientifically validates a key design feature in Ginkgosome™.

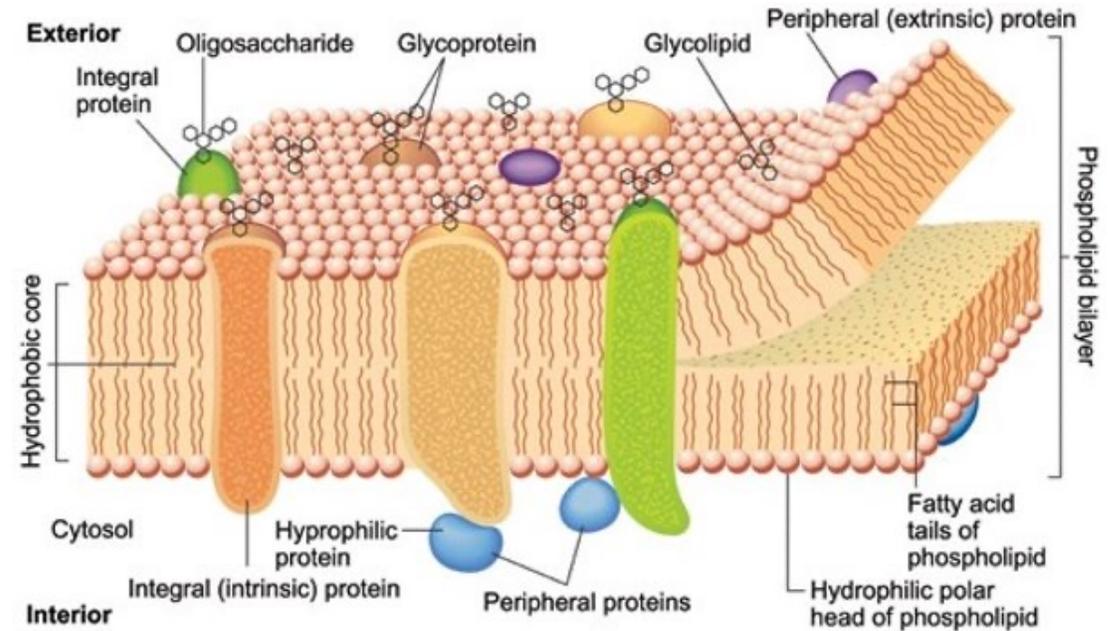

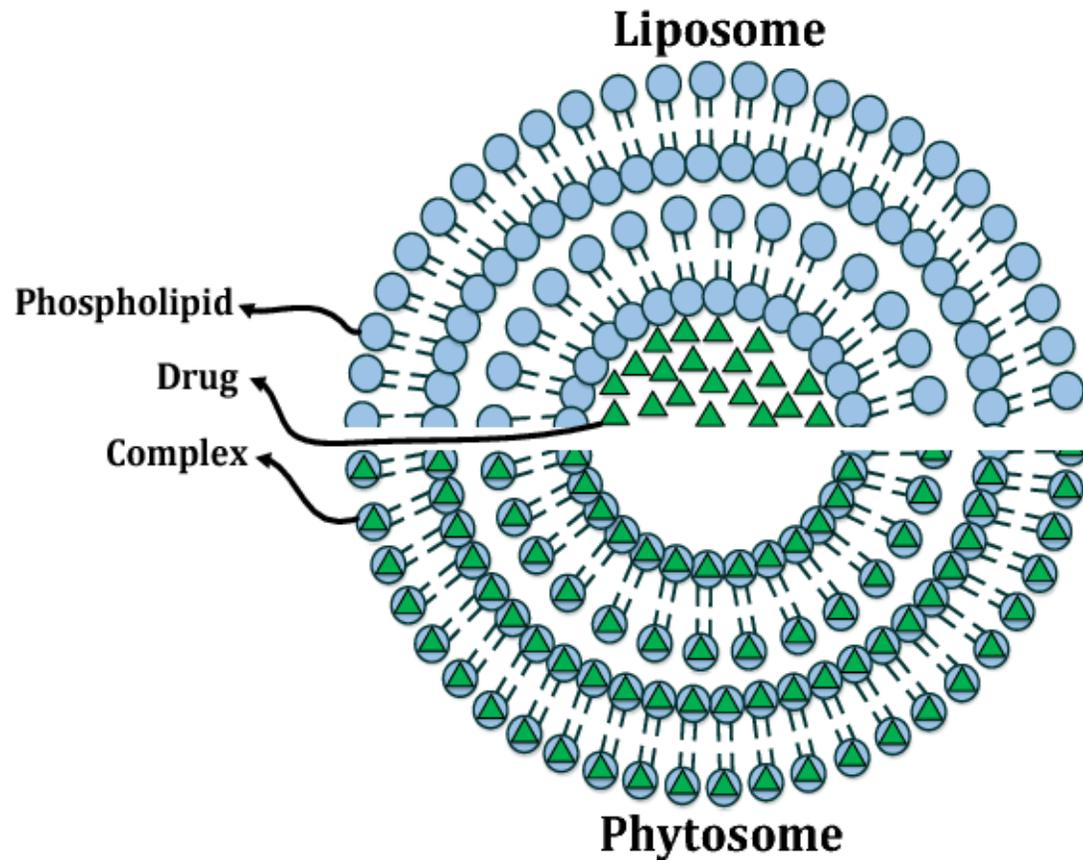

Analytically verified superior liposomal formation and structural integrity.

David Briskey^{1,2} and Amanda Rao^{1*} 

Abstract

Background: *Ginkgo biloba* extracts (GBE) have been used in traditional medicines for centuries. GBE has been shown to deliver protective effects against symptoms of age-related cognitive decline. Despite there being standardised extractions for GBE, there is still variability in the absorption and efficacy of different extracts. Following the development of a liposomal GBE (Ginkgosome™), the aim of this study is to investigate the absorption of the liposomal formulation compared to a comparator formulation of equal dose.

Methods: Thirteen healthy male and female volunteers completed this single equivalent dose, randomised, double-blind crossover study. Plasma concentrations were determined at baseline and at regular intervals over a 24-h period following ingestion of 120 mg of either a liposomal or comparator formulation.

Results: The liposomal formulation was able to increase plasma concentration of ginkgolide B and C by 1.9 and 2.2-fold compared to the comparator formulation.

Conclusion: The novel liposomal formulation is safe in humans and demonstrates superior absorption for the supply of GBE constituents compared to a comparator standardised formulation.

Abstract: Huperzine A (HupA), an alkaloid found in the club moss *Huperzia serrata*, has been used for centuries in Chinese folk medicine to treat dementia. The effects of this alkaloid have been attributed to its ability to inhibit the cholinergic enzyme acetylcholinesterase (AChE), acting as an acetylcholinesterase inhibitor (AChEI). The biological functions of HupA have been studied both in vitro and in vivo, and its role in neuroprotection appears to be a good therapeutic candidate for Alzheimer's disease (AD). Here, we summarize the neuroprotective effects of HupA on AD, with an emphasis on its interactions with different molecular signaling avenues, such as the Wnt signaling, the pre- and post-synaptic region mechanisms (synaptotagmin, neuroligins), the amyloid precursor protein (APP) processing, the amyloid- β peptide ($A\beta$) accumulation, and mitochondrial protection. Our goal is to provide an integrated overview of the molecular mechanisms through which HupA affects AD.

Huperzine A vs. contrôle

Cacher le texte étendu

Le médicament chinois huperzine A (un alcaloïde naturel, extrait de l'*Huperzia serrata*, de la famille des lycopodiacees) est un inhibiteur des acétylcholinestérases et aurait en outre des effets protecteurs contre le stress oxydatif. Pour cette raison, il a été testé en Chine comme médicament contre la maladie d'Alzheimer. Selon une *Cochrane Review*, l'huperzine A semblait avoir des effets positifs sur le fonctionnement cognitif, l'état général, le fonctionnement général et les problèmes du comportement chez des personnes avec la maladie d'Alzheimer. On n'a pas observé de différence significative entre l'huperzine A et le placebo au niveau des effets indésirables

Cette revue incluait 6 études (n = 454) dont la méthodologie était généralement de faible qualité et dont une seule étudiait une population suffisamment importante. Toutes les études ont été réalisées en Chine.

L'huperzine A (à la dose de 0,3 à 0,4 mg par jour) a été comparée au placebo, à l'acupuncture, à un traitement standard et en association à de la vitamine E, avec un placebo + vitamine E. Des différences significatives ont été observées entre l'huperzine A et le placebo pour le score MMSE (différence moyenne après 8 à 36 semaines = 2,81 ; p < 0,00001), ADAS-Cog (différence moyenne après 12 semaines = -5,36 ; IC à 95 % de -7,08 à -3,64), CIBIC-plus (OR après 12 semaines = 4,32 ; IC à 95 % de 2,37 à 7,90) et ADL (mesurées après 8 à 36 semaines, différence moyenne = -7,17 ; p < 0,00001).

Les effets indésirables étaient principalement cholinergiques (excitation, hyperactivité, obstruction nasale, nausées et vomissements, insomnie, anorexie, vertiges, soif et constipation), mais leur fréquence n'avait pas augmenté de manière significative dans le groupe huperzine par rapport au groupe placebo ■.

. D'autres études sont nécessaires, avec un plus long suivi sur l'efficacité, la posologie et l'innocuité dans de plus grandes populations, également en dehors de la Chine.

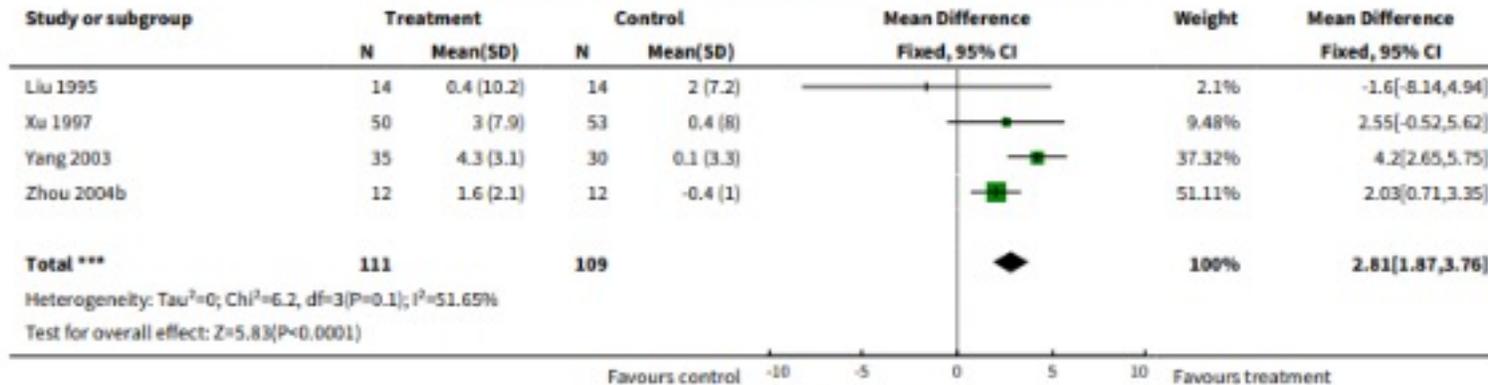

Une étude de petite taille n'a pas trouvé d'effet de l'huperzine A chez des patients avec une démence vasculaire ■.

10.11. Médicaments de la maladie d'Alzheimer

Les médicaments suivants sont utilisés dans la maladie d'Alzheimer:

- les inhibiteurs des cholinestéras
- la mémantine
- le *Ginkgo biloba*.

Les médicaments utilisés dans les troubles vasculaires (voir 1.10. Troubles vasculaires artériels) n'ont pas de place dans la maladie d'Alzheimer.

Positionnement

- Voir la Fiche de transparence "Démence", Folia de mai 2016 et Folia d'août 2018.
- La place de ces médicaments dans la maladie d'Alzheimer est limitée étant donné que leur effet est modeste et qu'ils présentent assez bien d'effets indésirables. Il n'y a pas d'arguments en faveur d'un effet neuroprotecteur ou d'un effet préventif sur le développement de la maladie d'Alzheimer, que ce soit dans la population générale ou chez des personnes présentant des troubles cognitifs légers.
- Il n'est pas clair dans quelle mesure les médicaments de la maladie d'Alzheimer améliorent la qualité de vie des patients et de leur entourage; ces médicaments ont été autorisés (enregistrés) sur la base de tests de la fonction cognitive et non sur la base d'études ayant comme critères d'évaluation le maintien du fonctionnement quotidien. Il n'est pas non plus démontré que ces médicaments peuvent retarder le placement en institution spécialisée.
- Les inhibiteurs des cholinestéras à action centrale ont un effet favorable modeste et temporaire sur les fonctions cognitives chez certains patients atteints d'une forme légère à modérément sévère de la maladie d'Alzheimer; on ne peut pas prédire quels sont les patients qui répondront au traitement. Les différents inhibiteurs des cholinestéras semblent comparables entre eux quant à leur efficacité.
- Avec les inhibiteurs des cholinestéras, un effet favorable modeste et temporaire a également été observé dans certaines études dans la démence liée à la maladie de Parkinson, dans la démence à corps de Lewy et dans la démence vasculaire. Dans la maladie de Parkinson, l'utilisation des inhibiteurs des cholinestéras peut être entravée par une aggravation des symptômes moteurs.

Fiche démence - CBIP

- Traitement médicamenteux de la démence 2011 (p.44)

Huperzine A

Pour la première fois, l'efficacité du médicament chinois 'huperzine A' a été étudiée en dehors de la Chine chez des personnes présentant une forme légère à modérément sévère de démence. Il ressort d'une étude de phase II randomisée en double aveugle, contrôlée par placebo, qu'après un traitement de 16 semaines, la plus faible dose étudiée (200 µg 2 fois par jour) n'était pas efficace; en revanche, la dose plus élevée (400 µg 2 fois par jour) était associée à un effet positif limité mais significatif sur la cognition. Pour les autres critères d'évaluation, on n'a pas observé de différences significatives entre l'huperzine A (les deux doses) et le placebo. Il n'y avait pas de différence significative en ce qui concerne l'apparition d'effets indésirables^a.

- a. Dans cette étude de phase II randomisée en double aveugle, 210 patients présentant une forme légère à modérément sévère de démence ont été randomisés en 3 groupes (huperzine A 200 µg 2 fois par jour, huperzine A 400 µg 2 fois par jour et un placebo). Après 16 semaines de traitement, seul le groupe ayant reçu la dose la plus élevée manifestait une différence limitée mais significative par rapport au placebo en ce qui concerne la cognition: avec l'huperzine A 400 µg, on a constaté une amélioration de 1,1 points sur le MMSE, par rapport à une diminution de 0,4 points dans le groupe placebo ($p = 0,007$); les résultats sur l'ADAS-Cog étaient tout juste non significatifs. On peut douter de l'impact clinique de cette différence limitée. La plus faible dose n'était pas associée à un effet significatif sur la cognition. On n'a pas observé de différences entre les deux groupes d'intervention et le groupe placebo en ce qui concerne le comportement, les AVQ et l'impression d'amélioration selon l'investigateur, ni en ce qui concerne l'apparition d'effets indésirables¹².

ABSTRACT

Objective: Huperzine A is a natural cholinesterase inhibitor derived from the Chinese herb *Huperzia serrata* that may compare favorably in symptomatic efficacy to cholinesterase inhibitors currently in use for Alzheimer disease (AD).

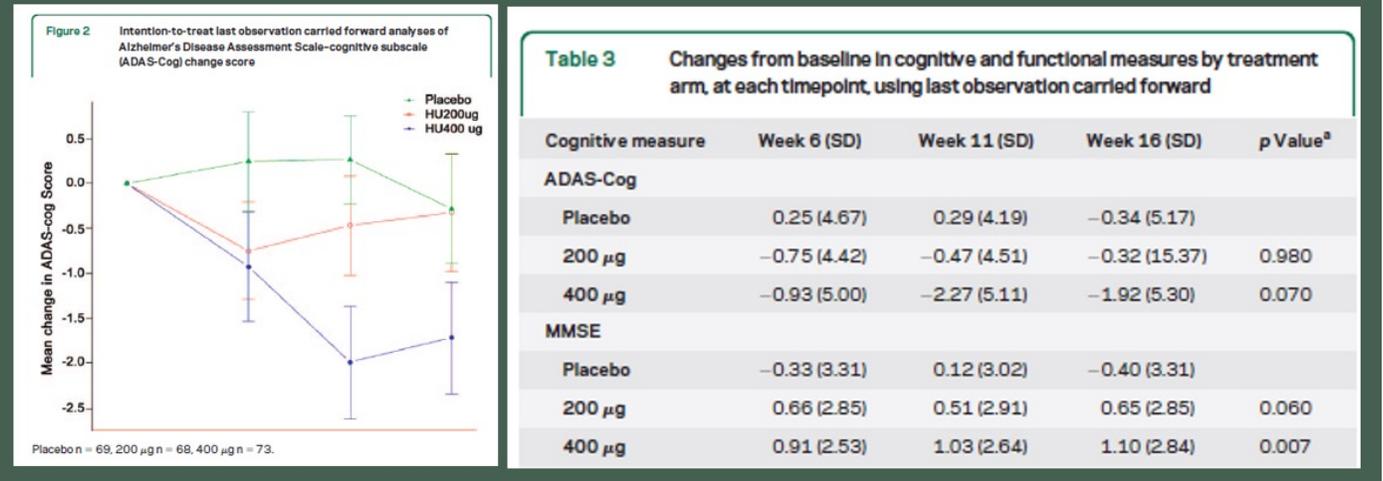

Methods: We assessed the safety, tolerability, and efficacy of huperzine A in mild to moderate AD in a multicenter trial in which 210 individuals were randomized to receive placebo (n = 70) or huperzine A (200 µg BID [n = 70] or 400 µg BID [n = 70]), for at least 16 weeks, with 177 subjects completing the treatment phase. The primary analysis assessed the cognitive effects of huperzine A 200 µg BID (change in Alzheimer's Disease Assessment Scale-cognitive subscale [ADAS-Cog] at week 16 at 200 µg BID compared to placebo). Secondary analyses assessed the effect of huperzine A 400 µg BID, as well as effect on other outcomes including Mini-Mental State Examination, Alzheimer's Disease Cooperative Study-Clinical Global Impression of Change scale, Alzheimer's Disease Cooperative Study Activities of Daily Living scale, and Neuropsychiatric Inventory (NPI).

Results: Huperzine A 200 µg BID did not influence change in ADAS-Cog at 16 weeks. In secondary analyses, huperzine A 400 µg BID showed a 2.27-point improvement in ADAS-Cog at 11 weeks vs 0.29-point decline in the placebo group (p = 0.001), and a 1.92-point improvement vs 0.34-point improvement in the placebo arm (p = 0.07) at week 16. Changes in clinical global impression of change, NPI, and activities of daily living were not significant at either dose.
